Objects as Maps

Objects as Maps

Jerry Cain and Eric Roberts CS 106J May 22, 2017

The Concept of a Map

- One of the most important applications of JavaScript objects uses them to associate pairs of data values. In computer science, the resulting data structure is called a *map*.
- Maps associate a simple data value called a *key* (most often a string) with a *value*, which is usually larger and more complex.
- Examples of maps exist everywhere in the real world. A classic example is a dictionary. The keys are the words, and the values are the corresponding definitions.
- A more contemporary example is the World-Wide Web. In this example, the keys are the URLs, and the values are the contents of the corresponding pages.

Exercise: Maps in the Real World

• Talk with your tablemates and come up with examples from the real world that fit the map paradigm.

Maps and JavaScript Objects

- In the context of CS 106J, the most obvious example of a map is the JavaScript object, which implements precisely the map concept. The keys are strings, and the values are arbitrary JavaScript values.
- When you use an object as a map, you supply the key as a string expression using the square-bracket notation, as in

map[key]

If the key is defined in the map, this selection returns the value. If no definition has been supplied, the selection returns the constant undefined.

 Map selections are assignable, so that you can set the value associated with a key by executing an assignment statement:

map[key] = value;

Using Maps in an Application Before going on to create new applications of maps, it seems worth going through the example from the text, which uses a map to associate three-letter airport codes with their locations. The association list is stored in a text file that looks like this: ATL=Atlanta, GA, USA ORD=Chicago, IL, USA URD=Chicago, IL, USA URD=Chicago, IL, USA CD=Paria, France DFW=Dallas/Ft Worth, TX, USA FRA=Frankfurt, Germany The AirportsCodes.js program shows how to read this file into a JavaScript object.

Symbol Tables

- Programming languages make internal use of maps in several contexts, of which one of the easiest to recognize is a *symbol table*, which keeps track of the correspondence between variable names and their values.
- The **symbolTable.js** application included in the example programs for this lecture implements a simple test of a symbol table that reads lines from the console, each of which is one of the following commands:
 - A simple assignment statement of the form var = number.
 - A variable alone on a line, which displays the variable's value.
 - The command list, which lists all the variables.
 - The command quit, which exits from the program
- The sample run on the next slide illustrates the operation of the symbolTable.js program.

Reading from the Console

- Implementing the **SymbolTable** application requires two new features that you have not yet seen:
 - 1. Reading a line from the console.
- 2. Iterating through all the keys in the map to implement list.
- Reading a line from the console is more difficult in JavaScript than it is in most languages, simply because JavaScript depends on an interaction model based on events and callback functions.
- The best strategy for reading a line of user input uses the console.requestInput method in the following form: console.requestInput(prompt, callback);
- If you need to read lines in a loop, the easiest way is to include another requestInput call in the callback function.

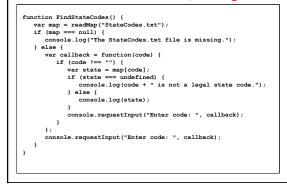

Iterating Through Keys in an Object

- One of the common operations that clients need to perform when using a map is to iterate through the keys.
- JavaScript supports this operation using an extended form of the for statement, which has the following form:

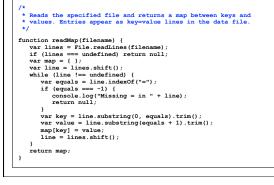

for (var key in map) {
 var value = map[key];
 ... code to work with the individual key and value ...

 In JavaScript, this extended form of the for loop can process the keys in any order.

The **FindStateCodes**.js Program

The **readMap** Function

Maps Can Be Fast

- If you think about the underlying implementation of maps, your first thought is likely to be that JavaScript looks through a list of keys to find the key in question and returns the corresponding value. That approach takes time proportional to the number of keys.
- Maps, however, can be implemented much more efficiently than that. As you will learn if you go on to CS 106B, you will learn that maps can be implemented so that the result is delivered almost instantly or, more accurately, so that the time required is constant no matter how many keys there are.
- To show that this result might in fact be possible, consider the state code example. If the state names are stored in an 26x26 array in which the indices correspond to the first and second letters in the code, finding the name is simply an array access.
